## **Document Revision History**

Revision	Date	Author	Description			
1.0	2019-11-15	Autochips	Initial Version			
1.1	2020-05-22	Autochips	1. Update Figure 10-4			
			2. Input impedance type value change to $50 \mathrm{k}\Omega$			
1.2	2022-09-02	Autochips	1. Update Table 8–5			
			2. Update Figure 9-2			
1.3	2022-10-30	Autochips	1. Add HPSOP36 pinning in Figure 4-2			
			2. Update Table 4–1 Pin description			
			3. Update Table 5–1 Thermal Characteristics			
			4. Update Table 6–1 Limiting values, HPSOP36 ESD			
			performance			
			5. Update Figure 11-1 Application circuit, add			
			HPSOP36 pin information			
			6. Add Figure 12-2 and Table 12–2			
1.4	2022-11-14	Autochips	Table 12-1 add note[2], "Plastic or metal protrusions			
			maximum per side are included"			
1.5	2022 - 11 - 25	Autochips	1. Update Table 2-1 cross talk, update Table 7-1			
			crosstalk			
			2. Update Figure 12-1 and Table 12-1, add Z parameter			
1.6	2023-02-03	Autochips	1. Add "AEC-Q100 qualified" in general feature list.			
			2. Update Table 8-6 8-7 8-8 8-9			
			3. Add 13 ordering information			
			4. Update Figture 12-1 and Table 12-1

### 1 General Feature List

The AC7325 is a 4X45W power amplifier, which uses a complementary DMOS output stage based on BCD process and intended for automotive applications. It has a high efficiency mode with full I<sup>2</sup>C-bus controlled start-up diagnostics. AC7325 can operate at low voltage, making this amplifier suitable for start-stop operation.

Thanks for the new high efficiency mode using a new switch technique, the dissipation is more than 65 % less than standard class AB solutions when used for front and rear correlated audio signals. Dissipation is less than standard BTL when used for uncorrelated (delayed) audio signals between front and rear. AC7325 also has been designed to be very robust against several kinds of misconnections.

- ♦ AEC-Q100 qualified.
- BCD technology and MOSFET output power stage.
- New high efficiency mode optimizing the uncorrelated signal.
- ♦ Operate in 3.3 V and 5 V compliant I<sup>2</sup>Cbus modes.
- Four hardware-selectable I<sup>2</sup>C-bus addresses.
- Independent selectable soft mute of front and rear channels.

- Clipping detect with selectable threshold:
   2 %, 5 % or 10 %.
- Selectable thermal pre-warning.
- Capable to operate down to 6V ("start stop").
- Speaker fault Diagnostic.
- Load detection during start-up diagnostics: open, short, normal.
- Selectable AC load (tweeter) diagnostic: low and high current mode.
- Offset detection.
- Thermal-, clipping- or load fault information (short load or to VCC or to ground) can be indicated on pin DIAG.
- Safe operation when ground/VCC missing.
- All amplifier outputs protection against short to ground, power and across load.
- All pins ok with short-circuit to ground.
- Temperature controlled gain reduction
- Selectable 7.5 V or 6 V minimum battery voltage operation.
- Overvoltage protection (safe on loaddump up to VCC = 50 V) with overvoltage pre-warning at 16 V.

### 2 Quick Reference Data

Symbol	Parameter	Conditions	Min.	Тур.	Max.	Unit
Vcc	Operating supply voltage	$RL=4\Omega$	6	14.4	18	V
$\mathbf{I}_{\mathbf{q}}$	Quiescent current	no load	-	250	350	mA
		RL = $4\Omega$ ; V <sub>CC</sub> = $14.4$ V; maximum power; Vi = 2 VRMS square wave	37	40	-	W
Ро	Output power	RL = $4\Omega$ ; V <sub>CC</sub> = 15.2 V; maximum power; Vi = 2 V RMS square wave	41	45	-	W
		RL=4Ω; V <sub>CC</sub> =14.4V; THD=1%	18	20	-	W
		RL=4Ω; V <sub>CC</sub> =14.4V; THD=10%	23	25	-	W
THD	Total	Po = 1 W to 12 W; fi = 1 kHz; RL = 4Ω; BTL mode	-	0.01	0.1	%
	harmonic	Po = 4 W; fi = 1 kHz; RL = $4\Omega$ ; high efficiency mode	-	0.03	-	%
Vn(o)	Output noise voltage	filter 20 Hz to 22 kHz;	-	40	60	μV
СТ	Cross talk	$F=1kH, Rg=600\Omega$	60	80	-	dB
U1	Closs talk	F=10kHz, Rg=600 $\Omega$	55	65	-	dB
GV	Voltage gain	-	25	26	27	dB
BW	Power bandwidth	-	-	-	100	kHz
ΔVο	Output	Pop during switch-on and switch-off, high efficiency mode	-	-	-	-
	voltage	From off to mute and mute to off	-	7.5	-	mV
	va11a01011	From mute to on and on to mute (soft mute)	-	7.5	-	mV

## 8 I<sup>2</sup>C-bus Bytes

AC7325 I<sup>2</sup>C\_SLAVE is used to control and diagnose the amplifier. I<sup>2</sup>C\_SLAVE write operation is used to update IB (instruction bytes) registers. I<sup>2</sup>C\_SLAVE read operation is used to send DB (diagnostic bytes) registers information to the host. There are 5 bytes IB and DB registers.

### 8.1 I<sup>2</sup>C instruction bytes

Bit	Description
D7	0 = Disable CD function when Vcc<10V 1 = Enable CD function when Vcc<10V
D6	-
D5	-
D4	-
D3	-
D2	0 = Disable AC load diagnostic 1 = Enable AC load diagnostic
D1	0 = Disable start-up diagnostics 1 = Enable start-up diagnostics
D0	0 = Turn off amplifier 1 = Turn on amplifier

#### Table 8–1 Instruction byte IB1

### 9 Functional Description

AC7325 is a four channels BTL audio power amplifier for car audio. It can work when battery voltage is as low as 6 V being so suitable for the start stop function. If battery drops below 6 V, the amplifier will mute without audible plops and can play automatically when the battery voltage back to 6V or above.

During amplifier turns on, the built-in diagnostics can be used to detect the load status. The status of each channel can be read separately. Any abnormal state such as open load, short load, load fault content, output DC offset, short to ground, and short to Vcc can be detected and reported by I<sup>2</sup>C.

AC7325 is protected against overvoltage, short-circuit, over temperature, and miss of ground or Vcc connections. The high temperature warning and clip detect threshold can be programmed by the  $I^2$ C-bus.

There are 4 selectable  $I^2C$  addresses that can be decided by a resistor connected to ADSEL pin and ground.

The high efficiency mode can reduce the conduction impedance and the dissipation. Comparing with standard bridge connection, working in HE mode will save power up to 65%.

### 9.1 Turn on and turn off sequence

STBY pin is 3.3V and 5V compatible. RC cells at STBY pin have to be always used in order to smooth the transition for preventing any audible noise.

The capacitor on SVR sets the turn on and turn off time. It helps to have pop free transitions. Its minimum recommended value is 10uF. Increasing the SVR capacitor value also increases the turn on and turn off time. This capacitor also contributes to power supply voltage ripple rejection. In order to reduce the turn on time, the impedance of SVR charging circuit is decreased to a low value until mute release. To keep device working continuously when the battery falls down (start stop), SVR is set as Vcc/4 to make sure the device can fully operate, only the maximum output power is reduced according to the available voltage supply.

The amplifier is turned on with IB1[D0]=1, the capacitor on the SVR is charged and SVR rises. Then the amplifier output rises to half power supply with output muted until SVR rises to a specific level. When the amplifier output has risen to the specific level, the mute state will be held when the I<sup>2</sup>C-bus bits are set to mute and will be released when the I<sup>2</sup>C-bus bits are set to unmute..

During turn on until mute is released, speaker fault detection is performed, and then the amplifier enters the play mode, AC load diagnostic can begin to be performed.

The amplifier is turned off with IB1[D0]=0, soft mute is enabled, then output falls and SVR is discharged.

If the battery voltage drops below the minimum operating voltage of 6V the amplifier is muted, the capacitor on SVR is discharged and the amplifier restarts when the battery voltage returns to the correct voltage.

Figure 9-1 Turn on and turn off sequence

### 9.2 Start stop function and low voltage operation

In automobiles, a start-stop system or stop-start system automatically shuts down and restarts the internal combustion engine to reduce the amount of time the engine spends idling, thereby reducing fuel consumption and emissions. The typical start stop battery curves is shown below in Figure 9-2.

AC7325 allows to go on playing when battery falls down to 6V during such conditions. If the battery falls below 6V, the amplifier can mute without producing pop noise and play automatically when the battery voltage back to 6V or above.

V1=12V/16V V2=7V V3=6V t1=2ms t2=15ms t3=50ms t4=1s t5=100ms

#### Figure 9-2 Start stop curve

#### 9.3 **Protection**

#### 9.3.1 Output protection and short-circuit protection

When the amplifier output shorts to power supply, ground, or across the load, the amplifier will close the shorted channel to avoid audible distortion. The short to power supply and the short to ground protection window prevents the channel a restart. When the output exits the protection window or short across load, the channel will turn on after 15ms to check if the short is still be present. If yes, the channel turns off again. The channel repeats the above process again and again until it exists short circuit, then returns to normal state. The 15ms interval period reduces the power consumption of the amplifier.

Short circuit and short circuit type information can be read via the  $I^2C$ -bus. The short circuit information can also be indicated on the DIAG pin. If the DIAG pin is enabled to indicate the fault information, set with IB2[D4] = 0, the DIAG pin will be pulled low once a short circuit occurs.

#### 9.3.2 Miss connect of Ground or Vcc

Miss connect of Ground or Vcc is a complex fault: the ground (or Vcc) is not connected and the ground (or Vcc) correctly but is connected to one of the amplifier outputs. In this short condition, the amplifier is not connected correctly so the protection circuit cannot work and protect the amplifier from this fault. It must resist this short current by the output stage itself.

 Page 28 of 46

 This document contains information that is proprietary to AutoChips Inc.
 Page 28 of 46

The output PDMOS and NDMOS transistors of AC7325 have been optimized for this fault and can avoid amplifier damage from this kind of fault.

#### 9.3.3 Thermal protection

Thermal protection function is achieved by attenuating the output signal swing (Figure 9-3).

Thermal attenuation starts to work when the junction temperatures rises above the normal operating range. This behavior can significantly limit the output power and protect the chip from being too hot with a method that does not interrupt the chip normal operation.

If the chip temperature rises too high to trigger the thermal protection, the output power shrinks which will cool the chip. When the chip temperature drops to a fixed point, the thermal attenuation stops. It's called thermal equilibrium and this point is called thermal equilibrium point.

As the chip temperature rises from a relatively lower level to high enough to trigger the thermal protection, it will first trigger the thermal warning before the output power is attenuated. As shown in Figure 9-3 two thermal warning thresholds can be programmed by I<sup>2</sup>C setting.

Figure 9-3 Thermal mute

#### 9.3.4 Overvoltage warning and load dump protection

When the battery power rises beyond the allowed maximum voltage, the chip normal operation will be interrupted to protect the chip internal devices from damage. This is called load dump protection. The maximum voltage is Vth(ovp) which is determined by the chip design and fabrication process.

When the battery power starts to rise from the typical value to Vovp, it will first trigger the overvoltage warning before load dump protection occurs and the threshold voltage is defined as

Vcc\_warn.

The overvoltage warning flag can also be sent out at the diagnostic output (DIAG pin) since the diagnostic output functionality is chosen through  $I^2C$  setting.

Even though the normal operation of the chip has been disabled during load dump conditions. The master can still communicate with the chip slave and all the digital is alive, which help users to read the status of chip channel output and overvoltage warning.

### 9.4 Diagnostics

#### 9.4.1 DIAG pin

Diagnostic information can be read via the I<sup>2</sup>C-bus, but many diagnostics messages can also be available at pin DIAG. These diagnostics information could be seen at pin DIAG as a logical NOR and pin DIAG is an OD(Open Drain) pin. If there is a failure, DIAG remains low and microcontroller can read the failure information via the I<sup>2</sup>C bus. Pin DIAG could also minimize the I<sup>2</sup>C bus traffic by being used as a microcontroller interrupt. Pin DIAG will be released when the failure is removed. The detailed trigger sources of pin DIAG can be seen from Table 9-1.

Diagnostic information	DIAG pin
Power-On Reset(POR)	After POR, pin DIAG remains LOW until amplifier starts (inverse of start-up bit)
Low battery	Yes
Clip detection	Can be enabled per channel (can be enabled below Vcc = 10 V, by IB1[D7]); default is 'blocked'
Temperature pre-warning	Can be enabled; default: Tj(AV)(pwarn) = 160°C
Short	Can be enabled; default is enabled
Speaker fault detection	No
Offset detection	No
Load detection	No
Overvoltage protection(20 V)	Yes
Overvoltage pre-warning (16 V)	Can be enabled; default is disabled
Maximum temperature protection (active)	Yes
Start-up diagnostics indication	No

#### 9.4.2 DC load detection during turn on

If IB1D1 is set to 1, the turn on diagnostics is enabled. AC7325 will report the load condition of all four channels while the diagnostics stage is ended. The load information can be known by reading I<sup>2</sup>C register. The load information is shown in

Table *9–2*.

AutoChips Confidential

 $\ensuremath{\mathbb{C}}$  2013 - 2022 AutoChips Inc.

#### Table 9-2 Short circuit detection thresholds

Short load		Normal load	Open load
0Ω —— 1.5Ω	$\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{\mathbf{$	3.2Ω —— 20Ω	80Ω —— ∞

There is a spike filter to remove any spike or glitch caused by switching relays in the wiring harness or EMC. Only the load information sustaining more than 10ms will be acknowledged and sent to  $I^{2}C$  register.

During turn on diagnostics stage, the invalid bits(see Table 9-3) are set, and "the start-up diag busy bit" (DB5[D5]) is set to 1 to show that turn on diagnostics stage is in progress. When turn on diagnostics stage is ended, the "start-up diag busy bit" is reset to 0.

Several abnormal statuses can make the turn on diagnostics invalid. They are overvoltage, Vcc<10V, POR or OCP trigger. In these cases, load information is set to 11. For example, if a start stop is occurred during the turn on diagnostics stage, Vcc will drop below 10V, so the load information DBx[D4:D5] is set to 11. In such case, repeating the turn on diagnostics may get a new load information result and DBx[D4:D5] will be rewritten.

Turn on diagnostics (IB1[D1]) and amplifier on (IB1[D0]) command are independent.

If IB1[D1:D0]=10 is sent, turn on diagnostics will be executed and after this turn on diagnostics stage ends, amplifier will return to turn off state.

If IB1[D1:D0]=11 is sent, turn on diagnostics will be executed first and after this turn on diagnostics stage ends, amplifier on command will be executed.

I <sup>2</sup> C bits		Description
DBx[D5]	DBx[D4]	
0	0	Normal load
0	1	Reserved
1	0	Open load
1	1	Invalid: overvoltage or $V_{cc} < 10$ V has
		occurred, or turn on diagnostics not
		completed, or OCP triggered.

#### Table 9–3 Load information I<sup>2</sup>C-bus bits

#### 9.4.3 Speaker fault detection

If one side of the speaker is connected to an output, the other side is grounded/powered when the other output of the channel is left open, speaker fault protection will be triggered to protect the speaker.

AutoChips Confidential © 2013 - 2022 AutoChips Inc. Page 31 of 46 This document contains information that is proprietary to AutoChips Inc. Unauthorized reproduction or disclosure of this information in whole or in part is strictly prohibited.

The speaker fault type can be read via I<sup>2</sup>C-bus. When the speaker fault protection is triggered, the amplifier channel does not turn off, just indicates in I<sup>2</sup>C. The amplifier will perform a speaker fault detection during amplifier start-up until mute is released. If the speaker fault current is 1A, the speaker fault will be identified.

#### 9.4.4 DC offset detection

The offset detection can be performed with or without (e.g. AMP is muted after start up) an input signal. The I<sup>2</sup>C bus DBx[D2] will be set if the I<sup>2</sup>C bus read that the output offset detection occurs. If the amplifier BTL output voltage is within a window with a threshold of 1.3 V (typical), the DBx[D2] latches are reset and their setting is disabled. Another case is that I<sup>2</sup>C bus read is performed and the offset bits are set at the first read time and still set after 1 s (the second read time), it means that the output did not cross the offset threshold window during the last 1 second. It means either a frequency below 1 Hz was applied (1 s I<sup>2</sup>C-bus read interval) or an output offset of more than 1.3 V is present. Detail information is presented in Figure 9-4.

**Figure 9-4 Offset detection** 

#### 9.4.5 AC load diagnostic

AC load diagnostic, set with IB1[D2], is targeted at detecting disconnection of 2-way speaker with AC coupled section, such as speaker with tweeters, more generally, woofer with parallel tweeter. When performing the AC load diagnostic, the high efficiency mode must be disabled by

AutoChips Confidential	© 2013 - 2022 AutoChips Inc.	Page 32 of 46
	This document contains information that is proprietary to AutoChips Inc.	
Unauthorize	d reproduction or disclosure of this information in whole or in part is strictly prohibited.	

setting IB5[D7] to 0.

The diagnostic principle is that a speaker with a tweeter, the part (woofer) other than the tweeter will become high impedance at high frequencies because this frequency band is out of its operating range. So if the tweeter is not connected, the impedance of the entire speaker will increase at high frequencies. Apply a voltage across the speaker can make a diagnostic based on the peak output current. There are high and low current levels to select form. When the output peak current of the amplifier triggers 500mA (with IB4[D1]=1) 64 times, the AC load diagnostic bit is set. When set to the low current level (with IB4[D1]=0), the trigger threshold becomes 275mA. The purpose of the 64 trigger count is to prevent false AC load diagnostic results when the input signal is turned on and off.

- High current level IB4 [D1] = 1
   Output current > 500 mApk, AC load detected
   Output current < 250 mApk, AC load not detected</li>
- Low current level IB4[D1]=0
   Output current > 275 mApk, AC load detected
   Output current < 100 mApk, AC load not detected</li>

The frequency and amplitude of the input signal depend on the impedance characteristic of specific speaker. To implement the above diagnostic function, a 19 kHz signal must be added to the input of the amplifier. AC load diagnostic is only performed after start-up mute is released and high efficiency mode is disabled during diagnostic. The AC load diagnostic information can be read by setting IB4[D4]=1. In the case IB4[D4]=0, the AC Load information cannot be read but preserved.

Figure 9-5 High current level, AC load impedance vs peak Vout\_app

AutoChips Confidential

Figure 9-6 Low current level, AC load impedance vs peak Vout\_pp

#### 9.4.6 Clip detection

When the input signal of the amplifier is large, the output of amplifier begins to distort near the power source or the ground, that is clipping distortion. The clipping information is sent directly to the DIAG pin, same as temperature and protection information. It can be programmed via the I<sup>2</sup>C-bus by disabling the temperature and protection information on the DIAG pin to indicate clipping information only. When the clipping distortion reaches the preset value, the DIAG pin will be pulled low.

There are three detect thresholds for the clipping detection can be selected by setting IB2[D7:D6] (2%, 5% or 10%). Meanwhile, IB2[D7:D6] set to 11 can disable clipping detection.

The clipping information will be blocked below 10V of power supply voltage. However, it can operate at the voltage less than 10V through I<sup>2</sup>C programming, but the accuracy of the clipping detection information is not guaranteed.

### 9.5 HE mode

HE mode is designed for a small signal whose amplitude less than several values avoiding output saturation. By closing the switch, two channels work in single ended mode, the output current flow from one end to the other through this switch.

In HE mode, lower current in connected channels will result in the less power dissipation. For this reason, one positive and one negative output are connected to the switch.

Therefore, to save power dissipation, the ideal condition is the two channels have the same signal. The current shared between different channels is maximum. Comparing with standard bridge connection, HE mode power dissipation will be saved up to 65%.

Now in many advanced audio systems, more intensive digital signal processor is used. This DSP

AutoChips Confidential © 2013 - 2022 AutoChips Inc. Page 34 of 46 This document contains information that is proprietary to AutoChips Inc. Unauthorized reproduction or disclosure of this information in whole or in part is strictly prohibited.

processing bring the introduction of different equalization and delays among different channels, this makes the saved current not so valid. By using a new HE structure, there is more chance to have two or more channels in HE mode. The connected terminals also have more independent currents summing for saving current when input signals are uncorrelated.

Figure 9-7 HE mode structure

#### 9.6 Address select

With the help of pin ADSEL, the amplifier can support address selection. The value of resistor connected between ground and pin ADSEL determines the address as shown in Table 9-4. Only when the battery power is above 6V, this function can be guaranteed.

R ADSEL	D6	D5	<b>D</b> 4	D3	D2	D1	<b>D0</b>	R/W	HEX
OPEN	1	1	0	1	1	0	1	0 = Write to AC7325 1 = Read from AC7325	DA
